## Load Xeva

Load Xeva library and data.

```
library(Xeva)
data(lpx)
head(modelInfo(lpx))
```

```

Models which belongs to same batch are in one list which is stored in expDesign slot. For example

```
print(batchNames(lpx))
```

```
## [1] "PHLC1106_P5" "PHLC111_P7" "PHLC119_P5" "PHLC153_P6" "PHLC181_P7"
## [6] "PHLC189_P5" "PHLC191_P5" "PHLC191_P7" "PHLC196_P5" "PHLC215_P5"
## [11] "PHLC229_P6" "PHLC235_P4" "PHLC655_P7" "PHLC82_P5"
```

To calculate angle between the treatment and control samples of this batch

```
batchNames <- batchNames(lpx)
expDesign <- expDesign(lpx, batchNames[1])
ang <- calculateAngle(lpx, expDesign, treatment.only = TRUE, plot=TRUE)
print(ang)
```

```
## $PHLC1106_P5
## $PHLC1106_P5$angle
## [1] 0.671583
##
## $PHLC1106_P5$plot
```

```
#par(mfrow=c(5,3))
for(I in batchNames)
{
  expDesign <- expDesign(lpdx, I)
  ang <- calculateAngle(lpdx, expDesign, treatment.only = TRUE, plot=TRUE)
  # print(ang)
}
```

Summarize Response of PDXs Get slop of each model and combine summarize all model slop which belongs to same patient by “mean”

```
lpdx_slop <- summarizeResponse(lpdx, response.measure = "slop",
                              group.by="patient.id", summary.stat = "mean")
```

Get angle between treatment and control model ids. For each batch it will give one angle value

```
lpdx_angle <- summarizeResponse(lpdx, response.measure = "angle")
```

Get mutation expression profile

```
ldxe_mut <- getMolecularProfiles(lpdx, data.type="mutation")
print(ldxe_mut)
```

```
